

4601 - Euclid

North America - Southeast - 2009/2010

In one of his notebooks, Euclid gave a complex procedure for solving the following problem. With computers, perhaps there is an easier way.

In a 2D plane, consider a line segment AB, another point C which is not collinear with AB, and a triangle DEF. The goal is to find points G and H such that:

- H is on the ray AC (it may be closer to A than C or further away, but angle CAB is the same as angle HAB)
- ABGH is a parallelogram (AB is parallel to GH, AH is parallel to BG)
- The area of parallelogram ABGH is the same as the area of triangle DEF

4601 - Euclid 1/2

Input

Input consists of multiple datasets. Each dataset will consist of twelve real numbers, with no more than 3 decimal places each, on a single line. Those numbers will represent the *x* and *y* coordinates of points A through F, as follows:

$$x_{A} y_{A} x_{B} y_{B} x_{C} y_{C} x_{D} y_{D} x_{E} y_{E} x_{F} y_{F}$$

Points A, B and C are guaranteed to not be collinear. Likewise, D, E and F are also guaranteed to be non-collinear. Every number is guaranteed to be in the range from -1000.0...1000.0 inclusive.

End of the input will be a line with twelve zero values (0.0).

Output

For each input set, print a single line with four floating point numbers. These represent points G and H, like this:

```
x_{\rm G} y_{\rm G} x_{\rm H} y_{\rm H}
```

Print all values to a precision of 3 decimal places (rounded, NOT truncated). Print a single space between numbers.

Sample Input

Sample Output

```
5.000 0.800 0.000 0.800 13.756 7.204 2.956 5.304
```
